COVID-19 Misinformation Detection

Caitlin Moroney

12/2/2020

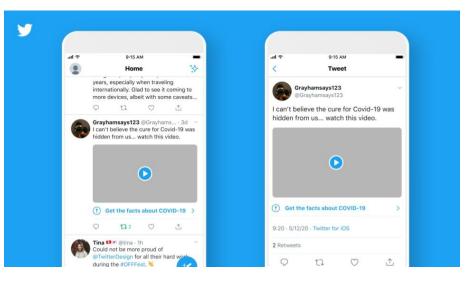

Figure 1: Twitter adds warning labels to tweets.

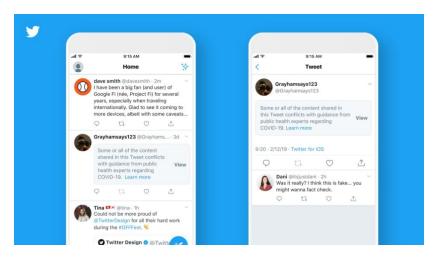

Figure 2: Twitter removes misleading content.

Dataset

- 560 tweets, perfectly balanced classes
- sample of 282,201 users in Canada
- tweets posted between January 1 March 13, 2020
- manually labeled as "reliable" or "unreliable"

Table 1: Misinformation rules from Boukouvalas et al. (2020)

| Linguistic Feature | Example from Dataset |
|---------------------------|---|
| Hyperbolic, intensified, | e.g., 'blame', 'accuse', 'refuse', 'catas- |
| superlative, or emphatic | trophe', 'chaos', 'evil' |
| language | |
| Greater use of punctua- | e.g., e.g., 'YA THINK!!?!!?!', 'Can we |
| tion and/or special char- | PLEASE stop spreading the lie that |
| acters | Coronavirus is super super super con- |
| | tagious? It's not. It has a contagious |
| | rating of TWO' |
| Strongly emotional or | e.g., 'fight', 'danger', 'hysteria', |
| subjective language | 'panic', 'paranoia', 'laugh', 'stupidity' |
| | or other words indicating fear, surprise, |
| | alarm, anger, and so forth |
| Greater use of verbs of | e.g., 'hear', 'see', 'feel', 'suppose', 'per- |
| perception and/or opin- | ceive', 'look', 'appear', 'suggest', 'be- |
| ion | lieve', 'pretend' |

Methodology

- raw text
- word embeddings
 - word-word co-occurrence matrix
 - latent variable methods
- tweet embeddings
- classification
- evaluation

Word-Word Co-occurrence Matrix

- text cleaning: remove stop words, lemmatize text, convert to lowercase, remove special characters, remove punctuation
- context window size: 1, 2, 4, 6, 10, 15, 20
- weighting: raw frequencies, PMI, PPMI
- Laplace smoothing: add-1, add-2
- shifted or **unshifted**: k = 5, k = 1
- start/end tokens

Latent Variable Methods

$$\begin{bmatrix} \mathbf{X} \\ (n \times n) \end{bmatrix} = \begin{bmatrix} \mathbf{U} \\ (n \times k) \end{bmatrix} \begin{bmatrix} \mathbf{D} \\ (k \times k) \end{bmatrix} \begin{bmatrix} \mathbf{V}^{\mathsf{T}} \\ (k \times n) \end{bmatrix}$$

$$\begin{bmatrix} \mathbf{U} \\ (n \times k) \end{bmatrix} = \begin{bmatrix} \mathbf{A} \\ (n \times k) \end{bmatrix} \begin{bmatrix} \mathbf{S} \\ (k \times k) \end{bmatrix}$$

Figure 3: Truncated Singular Value Decomposition followed by Independent Component Analysis.

Tweet Embeddings

A tweet embedding is the average of the word embeddings for the words that occur in that tweet.

$$\mathbf{v}_i = \frac{1}{T_i} \sum_{j=1}^{T_i} \mathbf{e}_j$$

Example tweet: "Covid is fake news."

$$\operatorname{tweet} \begin{bmatrix} v_{i1} \\ \vdots \\ v_{ik} \end{bmatrix} = \frac{\operatorname{covid} \begin{bmatrix} e_{11} \\ \vdots \\ e_{1k} \end{bmatrix} + \operatorname{is} \begin{bmatrix} e_{21} \\ \vdots \\ e_{2k} \end{bmatrix} + \operatorname{fake} \begin{bmatrix} e_{31} \\ \vdots \\ e_{3k} \end{bmatrix} + \operatorname{news} \begin{bmatrix} e_{41} \\ \vdots \\ e_{4k} \end{bmatrix}}{4}$$

Classification

- One-class classification: one-class support vector machines (OCSVM), isolation forest, & local outlier factor (LOF)
- Binary classification: SVM
- Evaluation: performance & explainability

LIME: Local Explainability

Figure 4: LIME output for unreliable tweet.

ICA: Global Explainability

We define the importance of the i^{th} target word as follows:

$$g_i = \frac{1}{k} \sum_{j=1}^k |a_{ij}|$$

where k is the number of SVD features (and therefore the number of ICA features), and $|a_{ij}|$ is the magnitude of the i^{th} word's importance in topic j.

Example: Tweet 170

CNBC ADVICE NOW: Coronavirus is the flu. Wash your hands. Book a vacation. We'll look back on this and laugh.

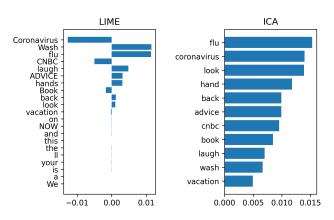

Figure 5: Comparing LIME and ICA explainability.

Explainability metric

Goal: value that captures how "explainable" a classifier's predictions are (with respect to human classification)

With penalty:

$$\frac{1}{N} \sum_{i=1}^{N} \frac{1}{T_i} \sum_{j=1}^{T_i} \mathbb{1}_{A}(w_j) - \mathbb{1}_{B}(w_j)$$

No penalty:

$$\frac{1}{N} \sum_{i=1}^{N} \frac{1}{T_i} \sum_{j=1}^{T_i} \mathbb{1}_{A}(w_j)$$

where A is the set of words that the classifier associated with the correct class according to LIME for tweet i, B is the set of words that the classifier associated with the wrong class according to LIME for tweet i, there are T_i words in tweet i, and there are N tweets.

Results

Table 2: One-class classification

| Model | AUC | Accuracy | F1 | Precision | Recall |
|------------------|-------|----------|-------|-----------|--------|
| OCSVM | 0.750 | 0.671 | 0.629 | 0.709 | 0.671 |
| Isolation Forest | 0.643 | 0.552 | 0.616 | 0.673 | 0.552 |
| LOF | 0.658 | 0.539 | 0.552 | 0.598 | 0.539 |

OCSVM used word embeddings of length 100; isolation forest and LOF used embeddings of length 50.

Results (continued)

Table 3: Binary SVM performance

| Dimensions | AUC | Accuracy | F1 | Precision | Recall |
|------------|-------|----------|-------|-----------|--------|
| 50 | 0.903 | 0.804 | 0.801 | 0.818 | 0.804 |
| 100 | 0.911 | 0.796 | 0.793 | 0.817 | 0.796 |
| 150 | 0.906 | 0.795 | 0.792 | 0.810 | 0.795 |
| 200 | 0.901 | 0.800 | 0.798 | 0.815 | 0.800 |
| 250 | 0.904 | 0.807 | 0.804 | 0.827 | 0.807 |
| 500 | 0.908 | 0.789 | 0.785 | 0.814 | 0.789 |

Results (continued)

Table 4: Binary SVM explainability

| Experiment | Penalty | No Penalty |
|-------------------------|---------|------------|
| 1: Correctly predicted | 0.331 | 0.534 |
| 1: Wrongly predicted | 0.222 | 0.278 |
| 1: Aggregated | 0.326 | 0.521 |
| 2: Correctly predicted | 0.356 | 0.593 |
| 2: Wrongly predicted | 0.074 | 0.315 |
| 2: Aggregated | 0.342 | 0.579 |
| 3a: Correctly predicted | 0.396 | 0.593 |
| 3a: Wrongly predicted | 0.444 | 0.500 |
| 3a: Aggregated | 0.399 | 0.588 |
| 3b: Correctly predicted | 0.378 | 0.619 |
| 3b: Wrongly predicted | 0.148 | 0.407 |
| 3b: Aggregated | 0.367 | 0.608 |

Future work

- local ICA explainability
- different word embeddings (e.g., BERT)
- different classifiers (e.g., neural net)
- improve explainability metric
